Text Data

The book is based on the concept of the new science of Coverage: radio astronomy from the physical approach. The information given is covered by the table of contents. The text was compared with Bernard Lovell's and J. A. Clegg's Radio Astronomy (1952), and the following new information found in it may be of interest: 1) V. L. Ginsburg and the author in 1946 independently proved that solar radio wave emission originates in the solar atmosphere and not in the photosphere (p. 61), and that the solar atmosphere is entirely

1/4

Radioastronomiya (Populyarnyy ocherk)

AID 382 - I

non-permeable to radio waves. This has been confirmed by observations made in 1947 by S. E. Khaykin and B. M. Chikhachev in Brazil during the total solar eclipse. 2) V. G. Fesenkov computed the thermal conductivity of the surface of the moon to be about 1000 times smaller than that of granite or basalt; only pulverized dust can have such a small thermal conductivity (p. 94). 3) A. A. Kalinyak, V. I. Krasovskiy, V. B. Nikonov obtained two photographs of the region of the Galactic center (pp. 107-109), one on a regular plate and the other with an infra-red filter; the latter shows that the infra-red rays are much less absorbed by the inter-stellar dust than are the visual rays.

4) The astrophysicist S. B. Pikel'ner showed that between inter-stellar gas clouds there exists a rarified medium with a density of 0.1 atom per cubic cm., which spreads far beyond and above the Galactic plane (p. 112). 5) Radio wave emission is scarcely absorbed when passing through enormous clouds of inter-stellar dust, in contrast to visual rays (p. 124). 96 diagrams, graphs and photoplates illustrate the text.

The author calls his text a popular sketch of the young science of radio astronomy and dedicates it to readers without a special education, but often makes rather complicated and advanced statements

Title

The extended radiation source, near the ℓ Geminorum is identified as a nebula, the latter being a remainder of the deflagration of Nova in

Periodical

Dokl. AN SSSR, 97, Ed. 1, 53 - 55, July 1954

Abstract

In connection with a new powerful radiation source, detected near the 7 Twins, and identified recently (E. Baldwin & D. Dewhirst, Nature, 173, 164, (1954) as a remnant of the Supernova deflagrated in our Galaxy system in 837, reference is made to an earlier work published in USSR in 1951 by G. A. Shayn and V. F. Gaze. These Soviet scientists succeeded in obtaining a photograph of the nebula containing the above radiation source. Reference is made to Lundmark's catalogue of Novae stars and to the discrepancy between the coordinates of the radiation source of the nebula, as given by Lundmark, and those of Nova 837. This discrepancy is explained as a result of Lundmark's failure to properly interpret an old original Chinese source, in which the position of the star was indicated. 13 references; 7 of these USSR references (1951 - 1954)

Title

: Nature of discrete sources of cosmic radio-radiction

Periodical : Dok. AN SSSR 98/3, 353-356, Sep 21, 1954

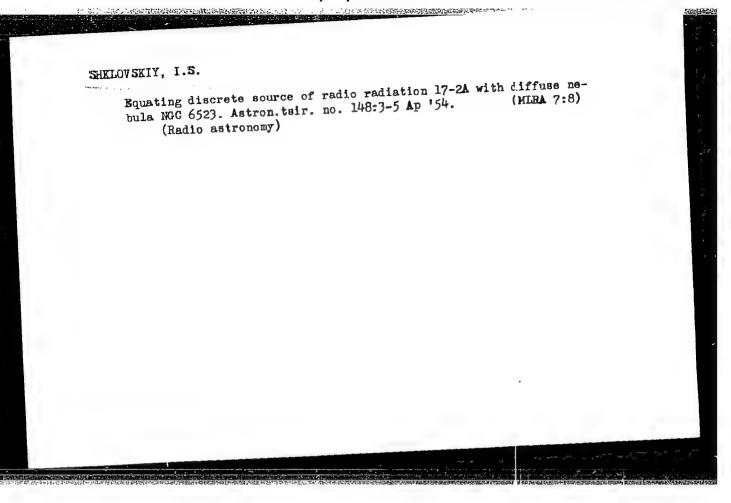

Abstract

: Various opinions and literature data, regarding the nature of discrete sources of cosmic radio-radiation, are presented. The mechanism of radioradiation of discrete sources, understood as a retarded radiation of relativistic electrons in magnetic fields, is discussed. Data regarding the probable radiation sources of the Cygnus and Cassiopeja constellations are included. The probability that a certain amount of charged particles diffused in interstellar gas may transform into cosmic rays was debated. Thirteen references:

Title

Occultation of two discrete sources of radiation by the moon

Periodical :

Astron. zhur. 32/1, 29-32, Jan-Feb 1955

Abstract

A new method of studying the nature of discrete sources of cosmic radiation is suggested. This method consists in the analysis of observed data on the occultation of such sources by the moon. Data for two powerful discrete sources of cosmic radiation is presented and discussed. One of themis the tourus-A ($\alpha = 5^h 31^m 34.5^{\circ}$; $\delta = 22^{\circ} 01^{\circ}$) the other is near the γ Cemini with the coordinates $\alpha = 6^h 13^m 37^s$; $\delta = 22^{\circ} 38^{\circ}$. Five references: 3 USSR and 2 USA (1951-1954). Tables.

It is suggested that Li and Be observed in solar atmosphere might be generated in the atmosphere itself by the "solar" cosmic rays produced during flares, when these rays collide with the O- and Fi-group nuclei. The flux of cosmic rays in solar atmosphere must be of considerable magnitude because the general magnetic field of the sum inhibits their exit into interstellar space It is to be expected that the highly "active" stars have very high values of the cosmic-ray flux; this would explain the existence of the pecular ("lithium" type) stars. The presence in solar atmosphere of large proportions of D has not been definitely proved; the author suggests looking for its lines in the flare spectra during solar eclipses.

: Problems of Radio Waves from the Metagalaxy Title

Orig Pub : Tr. 5-go soveshchaniya po vopr. kosmogonii. 1955. M., AN SSSR, 1956, 554-561

Abstract : The observed cosmic radiation can be arbitrarily subdivided into uniformly distributed radiation and radiation from discretee sources. A great majority of the 2000 discovered sources of the "radio galaxy" are object outside the galaxy. Analysis of observation data has shown that the sources of the galactic radio waves form a spherical system, and only a small fraction of the intensity in the direction of the galactic poles is due to metagalactic sources. Thid confirms the observed distributions of radiation from the M31 nebula. In the region of the galactic poles, out of a brightness temperature $T_b = 600^{\circ}$, the share of the metagalactic radiation is $T_b^m = 150-200^{\circ}$. This brightness temperature Th is due to the summary radiation from the "radio galaxies" and to radiation from the gathering of galaxies. The latter radiation cannot be considered as the joint radiation from the individual galaxies entering into the gathering; it is possible that this can be reduced to radiation from relativistic electrons in matagalactic magnetic fields. Ittis difficult to tell at this time what causes the observed brightness of the metagalaxy in the radio band, the radiation from the gatherings of galaxies, or radiation from discrete sources of the NGC 5128 or of the NGC 1316 Bibliography, 11 titles.

This transcript of a public lecture by the well-known Soviet astrophysicist Shklovskiy is published to provide a popular introduction to radio astronomy in general and to the recent developments and discoveries in this PURPOSE: new branch of astronomy.

The author gives a short review of the discovery of cosmic radio emission and its importance in the development of astronomy. He outlines the fundamentals of radio astronomy and the sources of cosmic radio emission. He describes the equipment now used in radio astronomy and devotes special COVERAGE: attention to sources of radio emission outside the solar system. He describes the results of observations of the density of cosmic radio emission and presents two hypotheses concerning sources of emission and their distribution in the universe. After presenting a brief outline of the nature of cosmic rays, he shows the role of radio astronomy in solving the problem of their origin and their relation to cosmic radio emission.

Rediation at 100 km from the surface of the earth is connected with the dissociation and formation of molecules. Variations of intensity of radiation are converted with temperature and pressure fluctuations in the upper atmosphere. Primary and secondary radiation of surorse and their nature are discussed. Security radiation can originate as a result of recombination processes, formation of an electric field, and chemical reactions of primary ions and excited products.

Shklovskiy, I. S. Elementary Processes in the Upper Atmosphere as Evidenced

In silition to common fluorescence originating in the selective absorption of uitrariolet soler radiation by atoms in the atmosphere with subsequent rereliabion of "softer" quanta, processes of resonance fluorescence take place in the upper atmosphere. With the detection of some lines in a twilight spectrum an estimate can be made of the number of Lyman quanta in short wave radiation from the sum.

Troitskaye, V. A. Short-Period Oscillations of the Earth's Klectro-

18

Simultaneous studies of telluric currents and magnetic records familitate the gouly of short-period oscillations. Experiments, installations for receiving telluric currents, and the basic principles of a proposed classification system for types of oscillations are discussed. The causal genetic relationship between various types of oscillations and the most favorable relative position of the earth and the Sun in exciting such oscillations were formulated.

21

Driatskiy, V. M. Ionosphere Near the Polar Region

Observations made from May 15, 1954 to April 14, 1955 on the drifting station SP-3 include vertical sounding of the atmosphere on a sliding frequency. During the period of minimum solar activity, the number of sun spots in the working period was 8.3. The vertical component of the earth's magnetic field changed from 56,612 to 3,919 % . The geomagnetic disturbance was much smaller then in polar observatories further south. The behavior of some ismospheric layers is nearly the same as in moderate latitudes and shows the same dependence on thm elevation of the sun. Ionization of various layers is pronounced and triple magneto-ionic splitting was observed rather frequently.

Card 4/9

The International Association (Cont.) Kalinir, Yu. D. Forecasting Secular Geomagnetic Variations

Variation in annual values of geomagnetic elements is the summary effect of variation in annual values or geomagnetic elements is the summary effect of changes in the geomagnetic field caused by internal agents (of) and by geomagnetic activity (of a). The latter could be completely eliminated by taking average values for 10-11 year cycles. The morphological examination of taking average values for 10-11 year cycles. such factors leads to the establishment of space-time relationships. The effects of internal forces in Eurasia are of a smooth, quasi-periodic character lasting a few decades and the geomagnetic activity follows an eleven year cycle. This makes it possible to forecast average values for a five year period with sufficient accuracy and to construct magnetic charts for the nearest epoch.

Nikol'skiy, A. N. Disbribution of Magnetic Disturbances in the Arctic

Irregular changes in the magnetic field are the main indication of disturbances in the high latitudes. The form and amplitude of the daily rate of disturbances are determined by the effect of the earth's permanent magnetic field on the incoming jets of solar particles. The diurnal variations in high latitudes are

card 5/9

30

25

33

The Triemational Association (Cont.) very complex. Observations near the pole suggest the existence of a second

zone of increased intensity and frequency of magnetic distrubances close to 80° geomagnetic latitude. This is well in accord with the studies of suroral and

ivanospheric disturbances and fits the theoretical findings of Alfven.

Ben'kowa, N. P. Electric Current in Magnetic Storms

The regular components of world magnetic and polar storms were studied in worldwide observations from 1932-1933. The potentials of these fields were computed and a system of polar storm currents was reconstructed. An increase in conductive ity with depth was determined and a break in it established at 900-1200 km, where 36

Guterberg and Repetti discovered a discontinuity for P-waves.

Weller, A. Ye. Hydrogen Radiation in the Auroral Spectrum

An investigation of hydrogen radiation in the auroral spectrum was conducted at 64° of geomagnetic latitude and in the neighbouring regions. The data obtained concerns the bright beam flash and the afterglow phases. Prolonged exposure spectograms (1-2 hours) in the region of 6,400-6,500A bear intense bands of the first positive system of N2; there are no evident signs of H d on the photographs or microphotographs, yet in all seven spectra the presence of H & photographs of microphotographs, yet in all seven spectra the presence of n & lines could be confirmed. Hydrogen radiation is regularly observed in the afterglow spectrum following a normally developing surora.

The International Association (Cont.) Ivanov, M. M. Magnetic Surveys at Sea in the Non-Magnetic Ship "Zarya"

Lack of magnetic observations on the oceans after 1929 makes the study of variations of the earth's magnetic field and the secular changes largely conjectural. Older observations made by the ships "Galileo" and "Carnegie", based on a 100 mile grid, do not reflect regional magnetic anomalies related to the structure or relief of the sea bottom. A proposal has been made for another survey to be conducted by a laboratory ship. The specially built ship "Zarya" with a 600 t. displacement was supplied with everything necessary for a month's voyage. The personnel consisted of 34 persons of which 9 were research workers. The instruments used for measuring magnetic phenomena are: for measuring declination, a 127 mm optical goniometric compass and a range finding compass for continuous recording and measurement of differences between the gyro-course and the magnetic course for the horizontal component, two double magnetic compasses; for measuring H and Z, a two-component magnetodynamic magnetometer and a "Zarya" already magnetodynamic T magnetometer with a self orientating indicator. conducted some experimental work in the Baltic and the North Sea, discovering a considerable number of anomalies. In the future it will make some observations in several regions of the supposed maximum secular movement of magnetic elements.

An investigation of the properties and energy dissipation of the galactic halo. (Cont.) field is connected with gas motions of the same energy. From the difference of H in the upper and lower. From the mean density of the gas $n \approx 0.01 \text{ cm}$ layers, the mean density of the gas $n \approx 0.01 \text{ cm}$ spitzer's main objection to high velocity is found.

Spitzer's main objection to high velocity gas motions in the halo is the strong energy is found. dissipation in supersonic motions. velocity of sound increases in a magnetic field. If the magnetic energy is equal to the kinetic, then the velocity of motion is the same as that of sound. In this case, according to (13), the rate of dissipation decreases 20 - 30 times, and there is also a corresponding decrease in the temperature and ionization of the gas. The energy dissipation cannot be compensated by outbursts of Novae or Supernovae nor by the radiation of hot stars. It is shown that the motions in the halo can evidently be supported by the waves from the Galactic nucleus, where large gas motions are observed. The increase in nonthermal radioemission towards the centre of the Galaxy is caused by the same motions, which increase the field strength. Some examples of halos, with incomplete ionization and in rapid motion, are given. The Large

AUTHOR: Shklovskiy, I. S.

On the Nature of the Emission from the Cancer Natura. (K Voprosu o Pripode Svecheniya Krabovidnoy Tumannosti.)

PERIODICAL: Astronomicheskiy Zhurnal, 1957, Vol.34, No.5,

ABSTRACT: In 1953 the author put forward a new interpretation of the optical emission of the Cancer nebula in the continuous spectrum. (Ref. 1) According to this interpretation the emission is due to radiation from very fast electrons (energy of the order of 1011-101eV) which move in a magnetic field. On the other hand radio emission is due to softer relativistic electrons having energies of about 10 - 10 ev. On the basis of this theory it is possible to predict a completely new effect namely: polarisation of the optical emission. In 1954 Dombrovskiy was first to observe polarisation of light from the Cancer nebula The effect was investigated by a number of authors (Refs. 4 - 8). Although the theory was developed further (cf. Ref. 7 and 10) by a number of workers, a whole series of problems still remain, unresolved. Some of these problems, such as the origin of cosmic rays, the nature of flares in supernovae etc. are considered It is shown that the contemporary Card 1/5 in the present paper.

33-5-4/19

On the Nature of the Emission from the Cancer Nebula.

hypothesis of the emission of relativistic particles from the supernova of 1054 meets with considerable difficulties. The formation of the well known "Wisp" which varies in brightness in the central part of the Gancer rebula as well as other variations of brightness in parts of the amorphous mass are explained by fluctuations of the magnetic field. A comparatively small increase in the magnetic field will cause a considerable increase in the total luminosity. Each relativistic electron during its "wanderings" in the magnetic fields of the Cancer mebula will meet different When it finds itself in a region where fluctuations of the magnetic field take place it loses energy by radiation. This loss is greater than that which takes place in the absence of fluctuations. In this way one can remove the difficulty connected with explaining the existence in contemporary Cancer methods of very energetic radiating electrons which as a result of major losses of energy could not have been "conserved" during the last 900 years. According to the arguments put forward by the author a given relativistic electron need not radiate during all the 900 years and hence may retain sufficiently high energy. For example, electrons with energy greater Card 2/5

33-5-4/12

On the Nature of the Emission from the Cancer Nebula.

relativistic electrons in the nebula which have an energy greater than E is given by

ristic electrons II.

than E₀ is given by

$$N(E > E_0) = \sum_{E=0}^{\infty} N(E) dE = K \sum_{E=0}^{\infty} \frac{dE}{E^{3.6}} = \frac{K}{2.6} \cdot E^{-2.6},$$

$$N(E > E_0) = \sum_{E=0}^{\infty} N(E) dE = K \sum_{E=0}^{\infty} \frac{dE}{E^{3.6}} = \frac{K}{2.6} \cdot E^{-2.6}$$

It follows that for energies greater than 10^7eV N = 8.10^{-4} cm⁻³, and for energies greater than 3.10^6 eV N = 8.10^7 cm⁻³. It is suggested that the mean concentration it is suggested that the mean concentration of soft cm. It is suggested that the mean concentration of sof relativistic electrons in the regions where fluctuations of the magnetic field takes place may be of the order of the magnetic field takes place may be of the order of the magnetic field is not considered it is suggested that as the properties of not considered it is suggested that as the properties of the field of contemporary Can nebula become better known the problem of the origin the field would be put on a more scientific basis. There are 1 figure, no tables, 13 references, 8 of which are Slavic.

TIPLE:

The Possible Influence Exercised by the Explosion of Supernovae on the Development of Life on the Earth (Vozmozhncye vliyaniye vspyshek sverkhnovýkh na evolýutsiyu zhizni na zemle)

PERIODICAL:

Doklady AN SSSR, 1957, Vol. 116, Hr 2, pp. 197 - 199 (USSR)

ABSTRACT:

It is at present considered to be proved fact that radio-frequency radiation and also optical radiation (with continuous spectrum) of the crab-shaped nebulae is caused by relativistic electrons which move in magnetic fields. Therefore, these nebulae (the remainder of the supernovae explosion of 1054) probably contain an enormous quantity of relativistic particles, i.e. of primary cosmic rays. This is true also for all other nebulae that are remainders of supernovae explosions. Recently also a radio-frequency radiation of the fibrous nebulae in the Bear were observed, which are without doubt, remainders of supernovae explosions which took place several thousand years ago. In such nebulae the concentration of the primary cosmic particles is probably 30 to 100 times as great as near the earth. It is quite possible that the sun with its planets may enter such a domain with increased concentration of primary particles as

Card 1/3

20-2-.9/50

The Possible Influence Exercised by the Explosion of Supernovae on the Development of Life on the Earth

a result of its motion within the galaxy. This happen whenever supernovae explode in the immediate neighborhood of the sun. The author is of the opinion that the number of supernovae explosions in our galaxy is abnormally large (within the last thousand years 1006, 1054, 1572, 1604 and 1843). Every 1000 years a supernovae probably explodes in a distance of atthe most 1000 parsec, and every 200 million years in a distance of at the most 8 parsec. The hard radiation (e.g. X-ray radiation) which reached the earth as a result of these explosions and the nebulae resulting therefrom (in the first stage of development) was probably considerably greater than the hard radiation of the sun. There may have been epochs of many hundreds of years during which cosmic radiation was a hundred times stronger than it is today. This could have had serious biological and, above all, genetical consequences. In order to double the mutation frequency of the long-lived genera, the intensity of cosmic radiation need only to be doubled or trebled. Therefore, a thousand years' intensification of cosmic radiation by several dozens of its former amount must produce devastating consequences for relatively long-lived kinds. Also the great "dyingout" of reptiles at the end of the cretaceous period might be due

TITLE:

The Interplanetary Medium and Some Problems of Physics of the Upper Atmosphere (Mezhplanetnaya sreda i nekotoryye voprosy fiziki verkhney atmosfery)

ABSTRACT:

PERIODICAL: Astronomicheskiy zhurnal, 1958, Vol 35, Nr 4, pp 557-571(USSR) The author studies the state of ionization of the interplanetary gas. The concentration of neutral hydrogen atoms is

 ~ 0.5 cm³, that of ionized hydrogen atoms ~ 200 cm³. The relative abundance of neutral atoms can in an essential degree be increased by neutralization processes of atoms on dust particles, caused by the contamination of the interplanetary plasma. The author discusses the relationship between the interplanetary gas and the planetary atmospheres. The renewal of the interplanetary gas by dissipation and accretion by sun

particles takes place in the course of 103-104 years. The presence of neutral hydrogen atoms in corpuscular streams, not deflected by the magnetic field of the earth, may be the origin of aurorae and similar phenomena. The Optical Observation of Artificial Earth-Satellites (Opticheskiye nablyudeniya iskusstvennykh sputnikov Zemli) AUTHORS: Uspekhi Fizicheskikh Nauk, 1958, Vol. 64, Nr 3, pp. 417-427 TITLE: PERIODICAL: The spatial coordinates of such satellites for various times (vŝsa) are determined by means of radiotechnical and optical methods. This work is dealing with the optical methods, which enable to determine the coordinates of satellites more exactly, on ABSTRACT: than do radiotechnical methods. The authors explicitly point out the importance of the exact position-finding of satellites. Above all, the analysis of the motion of satellites is important for the investigation of the shape of the earth. When the satellite is observed with an accuracy of 5", the coordinates of the observation place can be determined with an accuracy of several meters. An exact determination of the coordinates of satellites is first of all important for geodetic-and geophysical problems of geo-Card 1/3

53-64-3-1/8

The Optical Observation of Artificial Earth-Satellites

physics. This, however, / just one field of application for the exact coordinate determination. There is an interesting possibility for considerably increasing the brightness of satellites at dawn. It is the emergence of an "additional satellite" from the "main satellite". The additional satellite consists of a balloon of a thin aluminum-coated cover. At present such a balloon is realized which weighs 300 g, the apparatus for the gas filling included. But also bigger balloons of relatively light weight can be produced. Such a balloon has, however, because of its great braking effect, no substantial scientific value. The coordinates of the satellite can be determined by ding stars, The authors investigate the demands made on a system used for photographing satellites. Such a camera must take a fixed star of the 6th order within 1/300 of a second. By means of the analysis of the photographic picture an accuracy of + 1,5-2 seconds of arc can be obtained. The use of photoplates is to be preferred in the photographic investigation. Until November 1957, no data of the use of such cameras

Radicastronomical Investigations With the Aid of Artificial Earth Satellites

(Refs 1-8). The conditions for a receiving apparatus for the range 10 cm $< \lambda <$ 10 m are then discussed ($T_{\rm eff} = a\lambda^2 \cdot 8$, intensity $I_{\rm v} = \frac{2kT_{\rm eff}}{2} \sim \lambda^{0.8}$; with $\lambda \sim 3$ m, $T_{\rm eff}$ is of the order of 10³ degrees, at 30 cm $< \lambda <$ 100 m $T_{\rm eff} \sim 10^6$ to 10⁷ degrees; $I_{\rm v} \cong {\rm const}$; $\lambda >$ 100 m: $T_{\rm eff} \cong 10^7$ degrees). The authors further discuss radio-receiving apparatus. For $\lambda > 100$ m very low limiting values of the noise factor(F_n ~ 2) are obtained for coincidence superheterodyne receiving sets. For large \(\) wire antennae of several 10 m length would be necessary; as this is impossible in a Sputnik, frame antennae with ferrite core are used, which can be of very small dimensions ($\ell \sim$ 10 cm, weight 300 g). The axis of the frame is parallel to the metal surface of the Sputnik. Because of a Sputnik's own rotary motion also the position of the frame is modified which causes fluctuations of the intensity of reception. It is therefore necessary to know the orientation of the frame at every instant. The antenna will not receive a radiation for which it holds that $\mathcal{E}(f,\mathbb{N})=0$ at the place of reception. If the magnetic terrestrial field is

Card 2/3

Radioastronomical Investigations With the Aid of Artificial Earth Satellites

neglected, it holds that

$$\varepsilon(f) = 1 - \frac{4\pi e^2 N}{m(2\pi f)^2} = 1 - 8.10^7 \frac{N}{f^2}$$

Here N is the electron concentration, f - the frequency of the radiation received. In interplanetary space N~1 to 5.10^2 ,

 $\mathcal{E}(f)>0$, $f>f=9.10^4-2.10^5$ or $\lambda=c/f<\lambda=1.5$ to 5 km. When measuring f_0^o it is possible to calculate M according

to the aforementioned formula. The influence exercised by the terrestrial field complicates investigation, but this influence is not very considerable for relatively fast Sputniks. There are 11 references, 4 of which are Soviet.

ON THE MATURE OF HARD CORPUSCIES IN THE UPPER ATMOSPHERE I.S. Shklovsky, V.I. Krasovsky, Yu.I. Galperin, Svetlitzky, yE. M.

1. Investigations conducted by Soviet and American artificial earth satellites have led to the detection of a region of intensive corpuscular radiation commencing at an altitude of several hundreds of kilometres and consisting of two "balts".

2. An analysis of the spatial distribution of these belts permits drawing cartain canclusions concerning the mechanisms of generation and

"osoape" of hard corpuscles.

3. An analysis is given of the relationship between aurorae and streams of solar corpuscles, on the one hand, and the energy spectrum and concentration of hard corpuscles in the outer "belt", on the other.

Galculations are made on the generation of hard corpuscles in the inner "belt" on the basis of the mechanism of decay of albedo neutrons.

5. There is given an analysis of other possibilities of generation of hard corpuscles in the upper atmosphere. Investigations of High-Energy Heavy Nuclei in the Primary Cosmic Radiation Close to the Geomagnetic Equator (Guan, Marianas Islands) D. M. Haskin, P. L. Jain, E. Lohmann, Marcel Schein

In a large stack of nuclear emulsion exposed to the cosmic radiation at 102,000 feet near the geomagnetic equator, 540 tracks of high-energy heavy nuclei were located in a systematic scan and followed along the track. Report presented at the International Cosmic Ray Conference, Moscow, 6-11 July 1959

Shklovskiy, I. S., and Kurt, V. G. AUTHORS:

TITLE:

Determining atmospheric density at an altitude of 430 km by the method of diffusion of sodium

vapors

PERIODICAL:

Referativnyy zhurnal, Mekhanika, no. 1, 1962, 96, abstract 18660 (V sb. Iskusstv. sputniki Zemli. no. 3. M., AN SSSR, 1959, 66-76)

A method of determining atmospheric density by diffusion of sodium vapors is considered, and the authors assume that it can be used at altitudes of 200 - 600 km. On September 19, 1958, in the USSR, the first experiment was performed on a high altitude rocket, on density determination by the above method at an altitude of 450 km. The article describes the experiment, an altitude of, and observations of the sodium cloud after its instrumentation, and observations of the sodium cloud after its The relation is shown between the brightness of the

Card 1/3

formation.

Determining atmospheric...

center of the cloud and time by photographic and photo-electric recording and the dependence of total radiation on time. In the first few tens of seconds after the evaporation, the cloud was erregular and changing, but after approximately 100 sec., it became spherical; and also from that moment, total radiation flow. after a period of sharp rise, became constant. The radius of the cloud S varied with respect to time, according to the law $S=t^{1/2}$, which is characteristic for a diffusion process in the cloud. As an example, estimation of the density of air at an altitude of 430 km by the diffusion of clouds gives n=1.6 x altitude of 430 km by the diffusion of clouds gives n=1.6 x 10^8 cm⁻³ (or by more exact calculations, $n = 2.5 \times 10^8$ cm⁻³). In this determination of the air density by the diffusion of sodium vapor cloud method, a series of assumptions is made: temperature of the atmosphere is 1600 K; density of atmosphere within the limits of the cloud is constant (diameter of the cloud--100 km); force of gravity is neglected; size of atoms is taken as

Determining atmospheric...

 $a = 3.5 \times 10^{-8}$ cm, etc. The authors estimate the probable error in determining n as 30%. Therefore, $n = (2.5 \pm 0.75) \times 10^{-10}$ 10^8 cm⁻³. If it is assumed that the atmospheric composition is $\rho = (6.7 \pm 2) \times 10^{-15}$ mainly atomic nitrogen and oxygen, then g/cm^3 . From the analysis of retardation of the satellite 1958 \sim $(9 \pm 6) \times 10^{-15} \text{ g/cm}^3$ while, according to the data, at that height $\rho = 3 \times 10^{-15} \, \text{g/cm}$. Some results are given of density determination by satellite retardation, and their good agreement is noted with the retardation, and their good agreement is noted with the results obtained by the authors. 16 references. 68235 3/049/59/600/12/009/027 E032/E591 Shklovskiy, I.S., Krasovskiy, V.I. and Yu.I. Gal'perin On the Nature of Corpuscular Radiation in the Upper .3.9000 AUTHOR: PERIODICAL: Izvestiya Akademii nauk SSSR, Seriya geofizicheskaya, Soviet and American investigations carried out with the aid of artificial Earth satellites have led to the discovery of an intense belt of corpuscular rediation which begins at an altitude of 400-600 km (Refs 1-4). ABSTRACT: Recent results obtained with the aid of cosmic rockets have given the spatial distribution of the intensity of the hard corpuscular radiation surrounding the It transpired that there are two belts of corpuscular radiation. The first belt Earth (Refs 5 and 6). (the inner belt) forms an equatorial ring bounded (approximately) by the geomagnetic latitudes + 40°, According to Ref 5, the width of this belt is somewhat The belt has a concentration maximum at an altitude of about 3000 km (above the geomagnetic equator). The second (outer) belt extends up to 6-8 terrestrial radii and its concentration maximum is at a distance of Card1/6

Card2/6

68235 s/049/59/000/12/009/027

On the Nature of Corpuscular Radiation in the Upper Atmosphere 3.5-4 terrestrial radii. In order to explain the origin of the belt of fast charged particles surrounding the Earth, a number of authors have put forward the neutron decay hypothesis (Refs 7-9). This is the so-called trapped albedo theory of the radiation belt. However, an analysis of the spatial distribution of the particles in the two belts excludes, in the opinion of the present authors, the albedo theory. the presence of an equatorial belt means that the particles forming this belt "avoid" moderate and high geomagnetic latitudes. Apparently this is a result of the fact that geomagnetic disturbances and polar auroras at higher latitudes remove particles from the inner belt and prevent their accumulation. This means that the equatorial belt is supplied with particles only from below, i.e. from the lower layers of the spatial distribution of particles in the outer belt terrestrial atmosphere. clearly indicates an extra-terrestrial source. Again, the particles in the outer belt, once they appear in the magnetic trap at the distance of 3.5-4 terrestrial

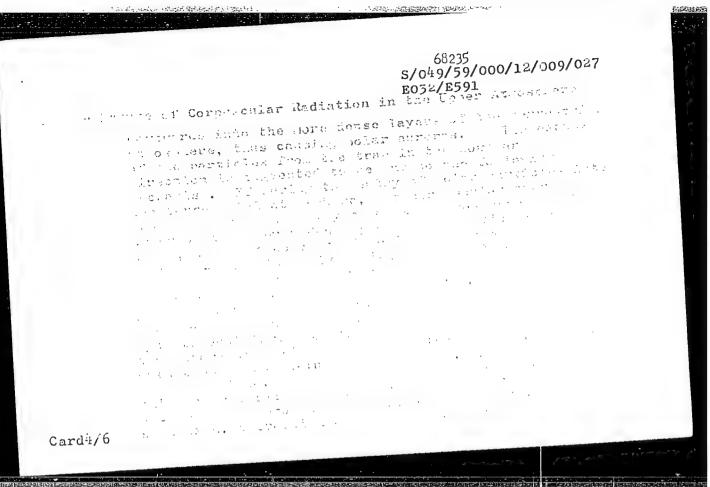

68235

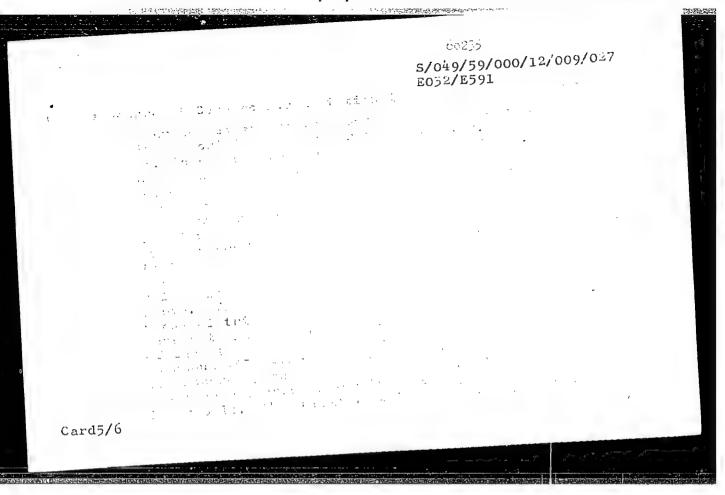

s/049/59/000/12/009/027 E032/E591

On the Nature of Corpuscular Radiation in the Upper Atmosphere

radii, will accumulate in this region over a longer interval of time than at the distance of 5-6 terrestrial radii since the frequency and amplitude of geomagnetic disturbances at latitudes of 50-60° are greater by a factor of several tens than in the zone of maximum This explains the repeatibility of polar auroras. observed position of the maximum in the outer belt, The difference in the origin of the particles in the two belts leads also to a difference in their energies. Thus, an analysis of the spatial distribution of the particles in the two radiation belts leads to the conclusion that the main reason for the escape of particles in the outer (and apparently also in the inner) zone are geomagnetic disturbances and the associated auroras. Of course in the case of the inner belt the relevant auroras are the low-latitude auroras which are relatively rare. During geomagnetic disturbances, the normal field at high altitudes is disturbed and the particles confined in the trap can escape both into the inter-planetary space and

Card5/6

68235

S/049/59/000/12/009/027 E052/E591

On the Nature of Corpuscular Radiation in the Upper Atmosphere

charged particles as a result of the interaction of cosmic rays with the atmosphere, leading to the formation of neutrons (other than those formed in stars). Meson decays are also a source of unstable neutral particles. Another more powerful source are nuclear explosions. There are thus two sources for the inner belt, the first of which is the trapped cosmic ray albedo which can supply approximately 2 x 10^{22} - 2 x 10^{25} electrons with energy up to 780 keV and 10^{20} - 10^{21} protons with energy up to 30 MeV during a time interval of 10^6 - 10^7 sec. The second source is the nuclear explosion source, which at times can considerably increase the intensity of the hard corpuscular radiation in the equatorial belt. It is pointed out that it would be very desirable to have further data on the identification and the energy spectrum in the equatorial belt. There are 1 table and 25 references, 11 of which are Soviet, 11 English and 1 French.

TITLE:

On Possible Mechanisms of Emission of Discrete Galactic Ob-

jects in the Spectral Region 1225 - 1350 A

PERIODICAL:

Astronomicheskiy zhurnal, 1959, Vol 36, Nr 2, pp 264-268 (USSR)

ABSTRACT:

The authors examine the possibility of explaining the emission of discrete galactic sources, observed in the spectral region 1225 - 1350 Å, by usual mechanics. However, this explanation requires the assumption that the absolute value of brightness of galactic sources in this spectral region were considerably overestimated. The measurings of the H_C line necessary for

the investigation were carried out by N.N. Shefov and V.S. Prokudina in the Zvenigorod station of the Institute for At-

mospheric Physics of the Academy of Sciences USSR.

TITLE: The Discovery in the Upper Atmosphere by Means of the Third Sputnik of Electrons Having an Energy of About 10 kev (Obnaruzheniye v verkhney atmosfere s pomoshch yu tret yego sputnika elektronov s energiyey okolo 10 kev)

PERIODICAL: Doklady Akademii nauk SSSR, 1959, Vol 127, Nr 1, pp 78 - 81 (USSR)

ABSTRACT:

In the third Soviet sputnik (which was launched on May 15, 1958)

an experiment concerning the direct discovery of electrons of not very high energy was carried out in the upper atmosphere (Refs 1,2,3). It is characteristic of this experiment that (Refs 1,2,3). It is characteristic of the experiment that practically only electrons of some dozens of key were recorded. The indicators used did not react to the X-ray radiation generated by these electrons in the atmosphere and in the shell of rated by these electrons in the atmosphere and in the shell of the sputnik. Therefore, thin fluorescence screens (ZnS, actitue sputnik) with 2 mg matter per 1 cm² were used. As the authors vated Ag) with 2 mg matter per 1 cm² were used. As the authors used aluminum foils of various thicknesses as absorbers, it was used aluminum foils of various thicknesses as absorbers, it was used aluminum foils of various thicknesses of electrons of not possible, besides the intensity of fluxes of electrons of not particularly high energies, to evaluate also the "equivalent"

The Discovery in the Upper Atmosphere by Means of the SOV/20-127-1-20/65
Third Sputnik of Electrons Having an Energy of About
10 key

energy of the electrons. The limiting diaphragms fitted before the indicators warranted the recording of corpuscles within a solid angle of 1/4 steradian. The radiotelemetric material determined furnished several results of great geophysical interest: Electrons of ~10 kev were detected in altitudes of from 470 to 1880 km above sea level. The lowest intensity was found over the geomagnetic equator in an altitude of ~1300 km above sea level. At the "equivalent" energy of ~20 kev its minimum amperage was estimated at 10⁻¹⁴a. cm⁻² steradian⁻¹. In medium and polar latitudes (up to 60° geomagnetic latitude) an amperage of 5.10 11a. cm 2 steradian and sometimes also of more than 10 a.cm 2 steradian is usual for electrons with an equivalent energy of 12 kev by night. With the construction of the measuring apparatus, such high intensities were not expected. Therefore, the intensities exceeded the apparatus scale, and the intensity and "equivalent" energy of the electrons recorded could not be evaluated. A diagram shows the dependence
